Received 30 August 1977

There is proposed a method of calculation of values of the integrals $F^0(4p, 4p)$, $F^2(4p, 4p)$, $R^1(4s, 3d, 3d, 3d)$, $R^1(4s, 4p, 4p, 3d)$, and $R^2(4s, 4p, 4p, 3d)$ in dependence on electron configuration of atoms (ions) of the first transition series. The obtained values of individual integrals are consistent with values of other Slater—Condon parameters obtained by analysis of atomic spectra.

В работе предложен метод расчета величин интегралов $F^0(4p, 4p)$, $F^2(4p, 4p)$, $R^1(4s, 3d, 3d, 3d)$, $R^1(4s, 4p, 4p, 3d)$ и $R^2(4s, 4p, 4p, 3d)$ в зависимости от электронной конфигурации атомов (ионов) первого переходного периода. Полученные величины отдельных интегралов консистентны с величинами параметров Слейтера—Кондона, полученными из анализа спектров атомов.

In the previous paper of this series [1] there were proposed regression functions for the dependence of Slater—Condon parameters (available from atomic spectroscopy data) on electron configuration of atoms (ions) of the first transition series.

The methods of quantum chemistry, which consider all the monocentric integrals of electron repulsion, require the knowledge of the Slater—Condon parameters $F^0(4p, 4p)$ and $F^2(4p, 4p)$, which cannot be determined because of the lack of experimental data for elements of the first transition series. There is also necessary [2] to know the values of the integrals $R^1(4s, 3d, 3d, 3d)$, $R^1(4s, 4p, 4p, 3d)$, and

$R^2(4s, 4p, 4p, 3d)$ which do not belong to Slater—Condon parameters and we cannot determine them by analysis of atomic spectra because they do not occur in expressions for energies of atomic terms. In this work there is suggested a procedure of calculation of such parameters in dependence on electron configuration of atoms (ions), which is consistent with analogous dependences proposed for other spectral available parameters [1].

Method and results

Theoretical values of the integrals $F^0(4p, 4p)$, $F^2(4p, 4p)$, $R^1(4s, 3d, 3d, 3d)$, $R^1(4s, 4p, 4p, 3d)$, and $R^2(4s, 4p, 4p, 3d)$ can be calculated by direct integration, using a particular type of atomic orbitals. The use of theoretical values of these integrals, however, would not be consistent with the use of empirical values of the other integrals. Moreover, theoretical values of these integrals are dependent on the basis of atomic orbitals, used for integration. We have tried to overcome these difficulties introducing the assumption that the ratio of theoretical values of two different types of integrals is approximatively the same as this quantity determined by analysis of atomic spectra

$$\left(\frac{\text{Integral}_A}{\text{Integral}_B}\right)_{\text{theor}} = \left(\frac{\text{Integral}_A}{\text{Integral}_B}\right)_{\text{exp}} \quad (1)$$

The validity of this relation was tested for some cases of pairs of Slater—Condon parameters for elements of the first transition series. Only such pairs of Slater—Condon parameters were considered, in which at least one equal atomic orbital occurs. Theoretical values were calculated using the basis of atomic orbitals of Richardson *et al.* [3, 4]. In this basis there were calculated the values of the Slater—Condon parameters $G^1(4s, 4p)$ and $F^2(4p, 4p)$ and the ratio of the theoretical values was obtained

$$\left(\frac{G^1(4s, 4p)}{F^2(4p, 4p)}\right)_{\text{theor}}$$

This ratio depends only on the charge of the atom and is independent of the atomic number. Therefore, this ratio was approximated as continuous function of the atomic charge

$$\left(\frac{G^1(4s, 4p)}{F^2(4p, 4p)}\right)_{\text{theor}} = \sum_{i=0}^2 B_i Q^i \quad (2)$$

In Table 15 there are listed the values of coefficients B_i and the correlation coefficient of this approximation. The values of the parameter $F^2(4p, 4p)$ we

estimate using relation (2), where for $G^1(4s, 4p)$ we place the values of approximative function for experimental values of this parameter (see Ref. [1]).

Analogous procedure was used for estimation of values of the parameter $F^0(4p, 4p)$. The ratios

$$\left(\frac{F^0(4p, 4p)}{F^0(4s, 4p)}\right)_{\text{theor}} \quad \text{and} \quad \left(\frac{F^0(4p, 4p)}{F^0(4p, 3d)}\right)_{\text{theor}}$$

were calculated for various atoms of the first transition series in the basis of Richardson's orbitals [3, 4]. These ratios were approximated by continuous functions of atomic number and atomic charge

$$\left(\frac{F^0(4p, 4p)}{F^0(4s, 4p)}\right)_{\text{theor}} = \sum_{i=0}^2 \sum_{j=0}^1 B_{ij} Z^i Q^j \quad (3)$$

$$\left(\frac{F^0(4p, 4p)}{F^0(4p, 3d)}\right)_{\text{theor}} = \sum_{i=0}^1 \sum_{j=0}^2 B_{ij} Z^i Q^j \quad (4)$$

The coefficients B_{ij} are listed in Tables 13 and 14. The numerical values of $F^0(4p, 4p)$ we obtain as the arithmetic mean of values obtained by both methods using relations (3) and (4), when we replace $F^0(4s, 4p)$ and $F^0(4p, 3d)$ by values obtained from approximative functions introduced in the previous paper of this series [1]. The use of the arithmetic mean for calculation of $F^0(4p, 4p)$ compensates errors originated in approximative character of the used function relations.

Values of the integrals $R^1(4s, 3d, 3d, 3d)$, $R^1(4s, 4p, 4p, 3d)$, and $R^2(4s, 4p, 4p, 3d)$ consistent with spectral values of the other integrals were for elements of the first transition series obtained by analogous procedure as the Slater—Condon parameters $F^0(4p, 4p)$ and $F^2(4p, 4p)$. For the ratios of theoretically calculated integrals in the basis of Richardson's atomic orbitals [3, 4] there were used functions of the type

$$F(Z, Q) = \sum_{i=0}^{N_Z} \sum_{j=0}^{N_Q} B_{ij} Z^i Q^j \quad (5)$$

where Z is the atomic number, Q is the charge of the atom, N_Z and N_Q are the optimum degrees of polynomials, obtained by maximization of the correlation coefficient. In Tables 16—24 there are listed coefficients B_{ij} of these functions, obtained by the least-squares method. Values of the R integrals are calculated as the arithmetic mean of all the approximations containing competent atomic orbitals.

In Tables 1—12 are under the symbol Theoretical listed values of the ratios of individual types of integrals, obtained as a result of the direct integration and under the symbol Calculated values obtained by approximative expressions. From the

magnitude of deviations we can conclude that the proposed regression functions are in a very good agreement with the theoretical values of the ratios of individual integrals.

In connection with the results shown in [1] we can enumerate values of all the monocentric integrals of electron repulsion for atoms of the first transition series for noninteger electron configurations obtained by population analysis in LCAO MO SCF methods.
