Received 12 February 1982

Accepted for publication 3 December 1982

Paper published on the occasion of the 30th anniversary of the foundation of the Faculty of Pharmacy, Komenský University, Bratislava

Conditions were found to separate dimethylammonioethyl alkoxycarbanilate chlorides by thin-layer chromatography on silica gel and cellulose. The $R_{M}$ values were calculated from the $R_{\mathrm{t}}$ and $\Delta R_{M}$ values for the methylene increment in homologic series of compounds. A linear relationship between the $\boldsymbol{R}_{\mathrm{M}}$ values from partition chromatography and the partition coefficient measured ( $\log P^{\prime}$ ) or the substitution constant $\pi$ was ascertained. The $R_{M}$ values were also employed for correlation with the anaesthetic activity $(\log U)$.

Найдены условия для хроматографического разделения диметиламиноэтиловьх эфиров алкоксифенилкарбамовьх кислот в тонком слое силикагеля и целлюлозы. На основании хроматографических величин $R_{t}$ бьли рассчитаны величины $R_{\mathrm{M}}$, а в гомологических рядах $\Delta R_{\mathrm{M}}$ для метиленового звена $-\mathrm{CH}_{2}-$. Между величинами $\boldsymbol{R}_{\mathrm{m}}$ и измеренньім коэффициентом разделения ( $\log P^{\prime}$ ) или константой замещения $\pi$ была установлена линейная зависимость. Величины $\boldsymbol{R}_{\mathrm{m}}$ были использованы и при корреляции с биологическим действием - анестетической активностью $(\log U)$.

Biologic activity of a compound can be, inter alia, expressed in terms of its physicochemical properties of electronic and steric structures [1]. A correlation between the chromatographic and other characteristic data, e.g. partition coefficient has also been reported [2]; the $R_{\mathrm{M}}$ values resulting from partition chromatography can be used instead of classic partition coefficients in correlations between physicochemical properties and biologic activity.

Chromatographic behaviour of basic esters of substituted carbamic acids on Silufol and cellulose sheets was investigated [3]. A linear dependence of the $R_{M}$ upon $\log P^{\prime}$, or substitution constant $\pi$ was found when investigating 38 com-
pounds of two various groups differing in the character of both the substituent at the aromatic ring (2-, 3-, 4-propyloxy to octyloxy groups) and the alcohol (2-morpholinoethanol and 2-N,N-dipropylaminoethanol); the $R_{M}$ values were also employed for correlation with biologic activity.

We studied [4] the synthesis and properties of piperidinoethyl alkoxyphenylcarbanilates (2-, 3-, 4-methoxy to decyloxy groups) and calculated the $R_{M}$ and $\Delta R_{M}$ values in homologic series using the $\boldsymbol{R}_{\mathrm{t}}$ values. The $\boldsymbol{R}_{\mathrm{M}}$ values obtained in this way were correlated with the partition coefficient $\left(\log P^{\prime}\right)$, surface tension $(\gamma)$, and biologic effect - the anaesthetic activity $(\log U)$.

In this paper, which is a continuation of preceding papers [3, 4], a further series of compounds differing in the number of carbon atoms of the substituent and in the position at the aromatic ring is examined. Preparation of these compounds and their biologic activity (the local anaesthetic effect) have already been published [5].

## Experimental

The procedure for chromatographic separation of compounds under study (Table 1) has been published previously [3]. The cellulose sheets for partition chromatography were impregnated with $40 \%$ formamide in ethanol ( $96 \%$ ) containing tris-hydroxymethylaminomethane (TRIS, $1 \%$ ), soaked up by filter paper and dried for 120 min in the air. Following mobile phases were employed: $S_{1}$ - isopropyl alcohol-diethylamine (9.5:0.5), $S_{2}$ - light petroleum-diethylamine (8.5:1.5), $S_{3}$ - light petroleum-diethylamine (8.75:1.25), $\boldsymbol{S}_{4}$ - 1-propanol. Experimental determination of the partition coefficient $\left(\log P^{\prime}\right)$ and the procedure for dissociation constant estimation have already been described [3].

## Results and discussion

Chromatographic parameters of a series of $N, N$-dimethylaminoethyl phenylcarbamates substituted in the respective positions 2-, 3-, and 4- by an alkoxyl group (methoxyl up to decyloxy) and their relationship to physicochemical parameters were investigated by adsorption and partition chromatography. Silica gel (the pre-coated Silufol (Kavalier, Votice) sheets UV 254) was found to be the well suited sorbent for thin-layer chromatography. Nevertheless, we did not succeed in finding a common system for separation of all substances; the most suitable systems for compounds substituted in positions 2-, 3-, and 4- were $S_{1}, S_{2}$, and $S_{3}$, respectively. The separation was good, the spots were round-shaped and sharp. Since the compounds under study differ in the homologic alkoxy series by one methylene group it was anticipated that the $R_{\mathrm{f}}$ value would be shifted towards higher values with the increasing number of carbon atoms. This anticipation proved to be correct (Table 1) and an almost linear enhancement of $\boldsymbol{R}_{\mathrm{f}}$ values was
ascertained in the 2 -substituted homologic series. Compounds substituted in positions 3- or 4- by a group containing one or two carbon atoms displayed an anomalous behaviour. The $R_{M}$ values (Table 1) and substituents constants $\Delta R_{\left.\mathrm{M}_{(1 \mathrm{CH}}^{2}\right)}$ were calculated from the $R_{\mathrm{f}}$ values (which are an arithmetic mean of 6 measurements). Fig. 1 shows the relationship of $R_{M}$ values on the number of carbon atoms in the alkoxyl group chain; the relationship is linear with the exception of the first two members of the homologic series, also differing in the $\Delta R_{\mathrm{M}_{\left(\mathrm{CH}_{2}\right)}}$ values ( $0.05-0.10$ ), when compared with those of other members (0.03-0.05).

Cellulose (the ready-made Lucefol Quick sheets) was found to be a suitable sorbent for partition chromatography and the spots were detected with Dragendorf reagent. Good separation of all the investigated compounds was achieved in the elution system 1-propanol. The Lucefol sheets were prior to the separation treated with $40 \%$ formamide containing TRIS ( $1 \%$ ). The $R_{M}$ (Table 1) and $\Delta \boldsymbol{R}_{\mathrm{M}\left(\mathrm{CH}_{2}\right)}$ values were calculated from the experimentally determined $R_{f}$ ones.

a) Procedure and calculation published in [3];b) $\bar{R}_{\mathbf{t}}$ - the mean value of six chromafograms.

Lipo-hydrophility is usually characterized by the partition coefficient $P^{\prime}$; that of the investigated series was determined by the classical method in a system consisting of polar and nonpolar solvents [3]. Considering the fact that the characteristic chromatographic value $R_{M}$ was employed for further correlations in this series, the validity of the relationship $R_{M} v s$. the number of carbon atoms of the alkoxyl substituent had to be verified (Fig. 2). This relationship is linear, the $\boldsymbol{R}_{\mathrm{M}}$

Fig. 2. Dependence of $R_{M}$ values from partition chromatography upon the number of methylene groups in the alkoxyl substituent.
For symbols see Fig. 1.
values decrease in all series, the methoxyl and ethoxyl groups being the exceptions. These $R_{\mathrm{M}}$ values do not lie on the line and differ in the $\Delta R_{\left.\mathrm{MCH}_{2}\right)}$ value by $0.05-0.10$ from that $(0.03-0.05)$ of the other members of the series.

Fig. 3 shows the dependence of $P^{\prime}$ upon $R_{M}$ on the basis of partition chromatography; this relationship could be considered linear. Mathematical expression of this relationship are the equations

| Compound |  | $r_{\mathrm{k}}$ | $s_{\mathrm{r}}$ |
| :---: | :--- | :---: | :---: |
| $1-10$ | $\log P^{\prime}=-8.0804 R_{\mathrm{M}}+2.1625$ | 0.963 | 0.102 |
| $11-20$ | $\log P^{\prime}=-11.4631 R_{\mathrm{M}}+2.3242$ | 0.906 | 0.173 |
| $21-30$ | $\log P^{\prime}=-5.3083 R_{\mathrm{M}}+2.3842$ | 0.920 | 0.183 |

Introduction of another physicochemical parameter in the correlation equations (1-3) was of no influence on the $\mathrm{p} K_{\mathrm{a}}$ values, since they minimally differ from each other (Table 1). By introducing the Hansch substitution constants $\pi$ into correlation with $R_{M}$ values following equations were deduced

Fig. 3. Dependence of $P^{\prime}$ upon $R_{M}$ from partition chromatography. For symbols see Fig. 1.

Fig. 4. Dependence of $\pi$ upon $R_{M}$ from partition chromatography. For symbols see Fig. 1.

| Compound |  | $r_{\mathrm{k}}$ | $\boldsymbol{s}_{\mathrm{r}}$ |
| :---: | :--- | :---: | :---: |
| $1-10$ | $\pi=-8.0780 R_{\mathrm{M}}+1.7166$ | 0.963 | 0.102 |
| $11-20$ | $\pi=-11.4631 R_{\mathrm{M}}+1.8782$ | 0.906 | 0.173 |
| $21-30$ | $\pi=-5.2239 R_{\mathrm{M}}+1.9398$ | 0.921 | 0.189 |

The linear course of this relationship is presented in Fig. 4. The relationship between the logarithm of the surface-local anaesthetic activity and $R_{M}$ values is expressed by the equations

Table 2
$\log P^{\prime}, \pi$, and $\log U$ values of dimethylammonioethyl alkoxycarbanilate chlorides

| Compound | $\log P^{\prime}$ | $\pi$ | $\log U$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.453 | 0.009 | 0 |
| 2 | 1.085 | 0.639 | 0 |
| 3 | 1.445 | 0.999 | 0 |

| 6 | 2.289 | 1.843 | 1.800 |
| 7 | 3.152 | 2.706 | 2.004 |
| 8 | 2.619 | 2.173 | 2.096 |
| 9 | 3.096 | 2.650 | 1.720 |
| 10 | - | - | 0 |
| 11 | - | - | 0 |
| 12 | 0.716 | 0.270 | 0.125 |
| 13 | 1.405 | 0.950 | 0.153 |
| 14 | 1.175 | 0.729 | 1.021 |
| 15 | 1.048 | 0.602 | 1.301 |
| 16 | 2.674 | 2.228 | 1.408 |
| 17 | 2.504 | 2.058 | 0 |
| 18 | 2.562 | 2.116 | 0 |
| 19 | 3.346 | 2.900 | 0 |
| 20 | - | - | 0 |
| 21 | 0.833 | 0.045 | 0 |
| 22 | 0.757 | 0.311 | 0 |
| 23 | 1.168 | 0.722 | 0 |
| 24 | 1.835 | 1.389 | 0 |
| 25 | 2.695 | 2.249 | 0 |
| 26 | 3.095 | 2.649 | 0 |
| 27 | 3.313 | 2.867 | 0 |
| 28 | - | - | 0.895 |
| 29 |  |  | 0 |
| 30 |  |  | 0 |
|  |  |  | 0 |

| Compound |  | $r_{\mathrm{k}}$ | $\boldsymbol{s}_{\mathbf{r}}$ |
| :---: | :--- | :---: | :---: |
| $1-10$ | $\log U=-5.1990 R_{\mathrm{M}}+0.9313$ | 0.615 | 0.279 |
| $11-20$ | $\log U=-0.8911 R_{\mathrm{M}}+0.4655$ | 0.116 | 0.375 |

As seen, the correlation between $\log U$ and $R_{M}$ values was not evidenced. Compounds 21-30 are not included, since they reveal a very low surface-local anaesthetic effect (Table 2). Based upon the experimental data, the $R_{M}$ values obtained from partition chromatography can directly be applied in the quantitative relationship between the structure and activity for expression of the lipo-hydrophility of the particular compound instead of the classical $\log P^{\prime}$ or $\pi$ parameters; the $R_{M}$ values can also be substituted into correlation equations for compounds the lipo-hydrophility of which has so far not been tabulated.
